Teaching the Old .NET Remoting New Exploitation Tricks

This repository provides further details and resources on the [CODE WHITE blog post of the same name](#) **Teaching the Old .NET Remoting New Exploitation Tricks**:

- `RemotingServer`: a restricted .NET Remoting server
- `RemotingClient_MBR0`: a client that creates a `MarshalByRefObject` on the server using a XAML gadget
- `RemotingClient_MBR0_Lazy`: a client that creates a `MarshalByRefObject` on the server using `Lazy<T>`
- `RemotingClient_MBVO`: a client that sends a serializable `MarshalByRefObject` *by value*

RemotingServer

A .NET Remoting server with restrictive configuration:

- `TypeFilterLevel.Low`: causes [CAS code access permission restrictions](#))
- marshaled server type is not `MarshalByRefObject`: renders `--uselease` and `--useobjref` of **ExploitRemotingService** unusable
- no existing client channel: also renders `--uselease` and `--useobjref` unusable (due to CAS restrictions)

RemotingClient_MBR0

A client that implements the trick of creating a `MarshalByRefObject` on the server side and coercing the server to serialize it. This requires the deserialization of a `DataTable` class that results in arbitrary XAML parsing, which creates the `MarshalByRefObject` instance and throws it in an exception retrievable from the response.

It creates a `WebClient` that can remotely read and write files on the server.

RemotingClient_MBR0_Lazy

A client that implements the trick of creating a `MarshalByRefObject` on the server side and coercing the server to serialize it. Opposed to the `RemotingClient_MBR0` above, it only

requires the deserialization of a `System.Lazy<T>` object, which creates an instance of the specified type argument `T` during serialization.

It creates a `WebClient` that can remotely read and write files on the server.

`RemotingClient_MBVO`

A client that implements the trick of sending a serializable `MarshalByRefObject` *by value* instead of *by reference* and coercing the server to serialize it.

It uses the `SoundPlayer` to cause a file access by remotely setting its `Location` property.
